METHOD FOR THE TREATMENT OF NEUROLOGICAL OR NEUROPSYCHIATRIC DISORDERS

The present invention relates generally to a method for the treatment and/or
5 prophylaxis of neurological or neuropsychiatric disorders, in particular neurological or
neuropsychiatric disorders associated with altered dopamine function.

The pineal body, situated in the epithalamus at the centre of the brain, synthesises
and releases melatonin into the general circulation only during nocturnal darkness,
10 irrespective of whether a species is nocturnal or diurnal in its behavioural activity pattern.
In mammals, the rhythm of pineal nocturnal melatonin secretion is generated by a
biological clock located at the suprachiasmatic nuclei (hereinafter referred to as "SCN")
of the anterior hypothalamus. After following a circuitous route through the brain, afferent
pathways of the conarian nerves originating from the superior cervical ganglia end in
15 sympathetic innervation on pinealocytes. In humans, the only natural phenomenon
presently known to inhibit melatonin release is bright light. Melatonin release appears to
be robust and resistant to change by a variety of potent stimuli. The stability of the
melatonin rhythm makes melatonin an ideal candidate as a biological timing hormone, a
role which is indisputable for rhythms in photo-sensitive seasonal breeding mammals and
20 has been postulated for daily rhythms in non-seasonal breeders.

Daily injections of melatonin entrains free-running locomotor activity rhythms of
rats housed in constant darkness or constant light, influences the speed and direction of re-
entrainment to phase shifts in the light-dark cycle and reorganises and recynchronises the
25 disrupted components of the circadian system. These entrainment effects are dependant
upon on the integrity of the SCN biological clock which is a structure containing high
affinity melatonin receptors. In addition to these effects of exogenous melatonin on the
pattern of locomotor activity, there are early unconfirmed reports that melatonin injections,
pineal extracts and pinealectomy affect the amount of locomotor activity. Although such
30 reports are unconfirmed, they raise the possibility of a more direct action on the locomotor
system *per se*, rather than the indirect effect via the SCN. This would be consistent with
the more recent reports involving animal models of movement disorders such as those

- 2 -

where a decrease in spontaneous motor activity in mice is found with both peripheral (1) and intranigral (2) injection of melatonin as well as melatonin blockade of L-Dopa induced movement (3) and melatonin modulation of apomorphine induced rotational behaviour (4). Against this background, early reports of amelioration of Parkinson's disease by
5 administration of high doses of melatonin appears possible (5). In view of the role of dopamine in Parkinson's disease and other motor disorders, a common link between each of these disorders is a change in dopamine function.

Clinical studies examining the role of melatonin in neuropsychiatric disorders have
10 been limited in number and are inconsistent in their reported findings and hypothesised role of this hormone. It was suggested by MacIsac (6) that melatonin was involved in the precipitation of many symptoms of schizophrenia. This hypothesis was in accordance with the conjecture that the pineal was overactive in this disorder (7). However, other clinical studies have revealed that nocturnal melatonin secretion is reduced in chronic
15 schizophrenia (8) and some have paralleled the negative symptoms of this disease with those of Parkinson's disease (9) indicating that melatonin provides a protective effect against the development of the negative symptoms of schizophrenia and Parkinson's disease from the time puberty commences (10). This hypothesis is supported further by findings implicating pineal deficiency in schizophrenia (11). Additional confusion has
20 arisen as to the role of melatonin in the aetiology of schizophrenia as a result of experiments where bovine pineal extract was administered to patient's suffering from this disorder causing a reversal of biochemical abnormalities and clinical improvement (12). However, later repetition of these studies did not yield results which were clinically meaningful (13).

25 The psychopharmacology of psychosis does not aid in clarifying the role of melatonin in these disorders. The administration of β -adrenergic blockers, sometimes used as an anti-psychotic medication, reduces plasma levels of melatonin (14) while chlorpromazine, increases melatonin (15). However, since other anti-psychotics do not
30 elevate melatonin concentrations (16), the hypothesis that melatonergic function is altered in schizophrenics and that effective medications might work via the melatonergic system (17) have gained little support.

- 3 -

The picture becomes further obscured when the results from studies whereby melatonin was administered for prolonged periods to patients suffering from Parkinson's disease are considered. Daily doses of 1000-1200mg of melatonin per day have been reported to produce a 20-36% amelioration of the clinical features (18) and a significant
5 reduction in tremor (19). However, replication of that work, with similar doses over the same time period did not improve the cardinal features of Parkinson's disease (20). It has also been claimed that pineal secretory activity was diminished in this disease (21) and that melatonin itself could be useful in alleviating the symptoms of Parkinsonism (22). Consideration of the findings from other research (23) where the relationship between
10 agonist therapy and melatonergic activity was examined, arrived at the conclusion that Parkinson's disease did not result from pathology of the melatonergic system. Later research (24) revealed no major changes in melatonin rhythm or changes in plasma melatonin concentrations after dopamine agonist therapy. Bearing in mind the antioxidant properties of melatonin (25) and the current trend in attempting to halt the progressive
15 degeneration of Parkinson's disease by implementing antioxidants (26), this deflates any attempt to explain Parkinson's disease on the basis of pathological function of the pineal.

The role of melatonin in clinical disorders of appetite is believed to be of minimal significance. While plasma melatonin concentrations are significantly reduced in the
20 sub-population of anorexics which exhibit depression(27), this has been attributed to the depression rather than a pathological feature of anorexia nervosa or anorexia bulimia(28). Changes in the circadian periodicity of melatonin secretion has been detected in about one third of patients suffering from anorexia nervosa or anorexia bulimia(29). However, the increase in melatonin was suggested as being due to chronic malnutrition or sustained
25 physical exercise and lends little support to the interpretation that pathophysiology of the melatonergic system plays a significant role in such disorders.

We have now discovered the specific mechanism by which melatonin may be exacerbating motor disability and a number of related disorders of motor function. This
30 finding provides a rational basis upon which neurological or neuropsychiatric disorders can be treated and is designed to block and/or inhibit the activity of melatonin.

- 4 -

According to one aspect of the present invention there is provided a method for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function which comprises subjecting a patient in need thereof to therapy which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof.

The present invention also provides the use of therapy which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof in the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function.

Throughout this specification, unless the context requires otherwise, the word "comprise", or variations such as "comprises" or "comprising", will be understood to imply the inclusion of a stated integer or group of integers but not the exclusion of any other integer or group of integers.

The neurological or neuropsychiatric disorders associated with altered dopamine function may include movement disorders, such as, Huntington's chorea, periodic limb movement syndrome, restless leg syndrome, Tourette's syndrome, Sundowner's syndrome, schizophrenia, Pick's disease, Punch drunk syndrome, progressive subnuclear palsy, Korsakow-s (Korsakoff's) syndrome, Multiple Sclerosis or Parkinson's disease; medication-induced movement disorders, such as, neuroleptic-induced Parkinsonism, malignant syndrome, acute dystonia, stroke, trans-ischaemic attack, akathisia or tardive dyskinesia; eating disorders, such as, anorexia cachexia or anorexia nervosa; and cognitive disorders, such as, Alzheimer's disease or dementia, for example, pseudo dementia, hydrocephalic dementia, subcortical dementia or dementia due to Huntington's chorea or Parkinson's disease; psychiatric disorders characterised by anxiety such as panic disorder, agoraphobia, obsessive-compulsive disorder, post traumatic stress disorder, acute stress disorder, generalised anxiety disorder and anxiety disorders due to other medical disorders, such as, depression.

- 5 -

When dopamine containing neurones of the brain undergo degeneration there are two immediate consequences. One is the interference of normal synaptic transmission which is ultimately characterised by a depletion of functional dopamine (accompanied by a change in receptor number, affinity, etc.) resulting in decreased neurotransmission thereby affecting normal synaptic relations with adjacent neurones. Various neurological and neuropsychiatric disorders such as Parkinsonism are currently viewed as being due to depletion of brain dopamine. However, in the present invention increased brain dopamine is used as the biological marker to point to the mechanism underlying the alleviation of motor impairment, and associated states of anxiety and depression. Therefore from this perspective the altered dopamine function associated with neurological or neuropsychiatric disorders is generally characterised by a change in dopamine function.

The therapy may involve subjecting the patient to an external therapy which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof, for example, light therapy, and/or the administration of an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof, such as, a melatonin antagonist, β -adrenergic antagonists, for example, propranolol or atenolol, calcium channel blockers or melanocyte stimulating hormone (MSH) and/or surgical ablation or destruction of the pineal gland (pinealectomy). The melatonin antagonist may include a melatonin analogue or metabolite or any other indolamine, neurotransmitter, neuromodulator, neurohormone or neuropeptide which has an affinity for melatonin receptors and thereby interferes with normal melatonergic function. The agent may be administered alone or in conjunction with light therapy or medicaments used in the treatment of neurological or neuropsychiatric disorders, such as, for example, domperidone, haloperidol, pimozide, clozapine, sulpiride, metaclopramide, spiroperidol or an inhibitor of dopamine neurotransmission.

The therapy may also be performed in conjunction with ablation or destruction of areas of increased dopamine function in the brain, and/or with a drug therapy which alters dopamine function, such as the administration of a dopamine receptor blocker (antagonist), especially those neuroleptics described as atypical, such as clozapine and/or with a drug therapy with a β -adrenergic receptor antagonist, such as atenolol.

- 6 -

The typical levels at which melatonin may be blocked and/or inhibited:

- (i) the level of the signal from the brain to the pineal where release takes place;
- (ii) the level where synthesis takes place at the pinealocyte; and
- (iii) the level of the occupancy of receptors.

5

Thus, the therapy may block and/or inhibit not only melatonin itself, but precursors used in the production of melatonin, such as, for example, tryptophan, 5-hydroxytryptophan, serotonin or N-acetylserotonin or metabolic products resulting from the breakdown of melatonin including enzymes or other catalysts, such as, for example, tryptophan hydroxylase, aromatic amino acid decarboxylase, N-acetyltransferase and hydroxyindole-O-methyltransferase. An example of products resulting from the breakdown of melatonin is 6-hydroxymelatonin sulphate.

In yet another aspect of the present invention there is provided a method for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function which comprises administering an effective amount of an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof and a drug which alters dopamine function and optionally light therapy to a patient in need thereof.

20

According to another aspect of the present invention there is provided a method for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function which comprises administering an effective amount of an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof and optionally light therapy to a patient in need thereof.

25

The present invention further provides a method for the preclinical diagnosis of a neurological or neuropsychiatric disorder associated with dopamine function which includes the step of administering melatonin to a patient suspected of having such disorder.

30

Melatonin is administered at a predetermined time of day to induce a mild transient form of the disorder, followed by the assessment of the efficacy of a particular therapy

- 7 -

which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof.

5 The present invention also extends to the use of an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof in the manufacture of a medicament for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function.

10 The patient may be a human or an animal such as a domestic or wild animal, particularly an animal of economic importance.

An "effective amount" of the agent is an amount sufficient to ameliorate and/or inhibit the neurological or neuropsychiatric disorder.

15 The agent may be administered for therapy by any suitable route, including oral, implant, rectal, inhalation or insufflation (through the mouth or nose), topical (including buccal and sublingual), vaginal and parenteral (including subcutaneous, intramuscular, intravenous, intrasternal and intradermal). It will be appreciated that the preferred route will vary with the condition and age of the patient and the chosen agent.

20

The agent may be administered in the form of a composition, together with one or more pharmaceutically acceptable carriers, diluents, adjuvants and/or excipients.

25 Thus, according to a further aspect of the present invention there is provided a pharmaceutical or veterinary composition for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function which comprises an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof in association with a pharmaceutically or veterinary acceptable carrier, diluent, adjuvant and/or excipient.

30

The carrier, diluent, adjuvant and/or excipient must be pharmaceutically "acceptable" in the sense of being compatible with the other ingredients of the composition

- 8 -

and not injurious to the subject. Compositions include those suitable for oral, implant, rectal, inhalation or insufflation (through the mouth or nose), topical (including buccal and sublingual), vaginal or parenteral (including subcutaneous, intramuscular, intravenous and intradermal) administration. The compositions may conveniently be presented in unit dosage form and may be prepared by methods well known in the art of pharmacy. Such methods include the step of bringing into association the agent with the carrier which constitutes one or more accessory ingredients. In general, the compositions are prepared by uniformly and intimately bringing into association the agent with liquid carriers, diluents, adjuvants and/or excipients or finely divided solid carriers or both, and then if necessary shaping the product.

Compositions of the present invention suitable for oral administration may be presented as discrete units such as capsules, sachets or tablets each containing a predetermined amount of the agent; as a powder or granules; as a solution or a suspension in an aqueous or non-aqueous liquid; or as an oil-in-water liquid emulsion or a water-in-oil liquid emulsion. The agent may also be presented as a bolus, electuary or paste.

A tablet may be made by compression or moulding, optionally with one or more accessory ingredients. Compressed tablets may be prepared by compressing in a suitable machine the agent in a free-flowing form such as a powder or granules, optionally mixed with a binder (e.g. pregelatinised maize starch, polyvinylpyrrolidone or hydroxypropyl methyl cellulose), fillers (e.g. lactose, microcrystalline cellulose or calcium hydrogen phosphate), lubricants (e.g. magnesium stearate, talc or silica), inert diluent, preservative, disintegrant (e.g. sodium starch glycollate, cross-linked povidone, cross-linked sodium carboxymethyl cellulose), surface-active or dispersing agents. Moulded tablets may be made by moulding in a suitable machine a mixture of the powdered compound moistened with an inert liquid diluent. The tablets may optionally be coated or scored and may be formulated so as to provide slow or controlled release of the agent therein using, for example, hydroxypropylmethyl cellulose in varying proportions to provide the desired release profile. Tablets may optionally be provided with an enteric coating, to provide release in parts of the gut other than the stomach.

Liquid preparations for oral administration may take the form of, for example, solutions, syrups or suspensions, or they may be presented as a dry product for constitution with water or other suitable vehicle before use. Such liquid preparations may be prepared by conventional means with pharmaceutically acceptable additives such as suspending
5 agents (e.g. sorbitol syrup, cellulose derivatives or hydrogenated edible fats); emulsifying agents (e.g. lecithin or acacia); non-aqueous vehicles (e.g. almond oil, oily esters, ethyl alcohol or fractionated vegetable oils); and preservatives (e.g. methyl or propyl-p-hydroxybenzoates or sorbic acid).

10 Compositions suitable for topical administration in the mouth include lozenges comprising the agent in a flavoured basis, usually sucrose and acacia or tragacanth gum; pastilles comprising the agent in an inert basis such as gelatin and glycerin, or sucrose and acacia gum; and mouthwashes comprising the agent in a suitable liquid carrier.

15 For topical application for the skin, the agent may be in the form of a cream, ointment, jelly, solution or suspension.

For topical application to the eye, the agent may be in the form of a solution or suspension in a suitable sterile aqueous or non-aqueous vehicle. Additives, for instance
20 buffers, preservatives including bactericidal and fungicidal agents, such as phenyl mercuric acetate or nitrate, benzalkonium chloride or chlorohexidine and thickening agents such as hypromellose may also be included.

The agent may also be formulated as depot preparations. Such long acting
25 formulations may be administered by implantation (e.g. subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the agent may be formulated with suitable polymeric or hydrophobic materials (e.g. as an emulsion in an acceptable oil or ion exchange resins), or as sparingly soluble derivatives, for example, as a sparingly soluble salt. Preferably, the agent is administered in the form of a polymeric implant, such as,
30 microsphere adapted for sustained or pulsed release to those parts of the central nervous system where dopamine is present, for example, substantia nigra, globus pallidus or nucleus caudatus.

Compositions for rectal administration may be presented as a suppository or retention enema with a suitable non-irritating excipient which is solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum to release the agent. Such excipients include cocoa butter or a salicylate.

5

For intranasal and pulmonary administration, the agent may be formulated as solutions or suspensions for administration via a suitable metered or unit dose device or alternatively as a powder mix with a suitable carrier for administration using a suitable delivery device.

10

Compositions suitable for vaginal administration may be presented as pessaries, tampons, creams, gels, pastes, foams or spray formulations containing in addition to the agent such carriers as are known in the art to be appropriate.

15

Compositions suitable for parenteral administration include aqueous and non-aqueous isotonic sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats and solutes which render the composition isotonic with the blood of the intended subject; and aqueous and non-aqueous sterile suspensions which may include suspending agents and thickening agents. The compositions may be presented in unit-dose or multi-dose sealed containers, for example, ampoules and vials, and may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example water for injections, immediately prior to use. Extemporaneous injection solutions and suspensions may be prepared from sterile powders, granules and tablets of the kind previously described.

20

Preferred unit dosage compositions are those containing a daily dose or unit, daily sub-dose, as hereinabove described, or an appropriate fraction thereof, of agent.

25

The agent may also be presented for use in the form of veterinary compositions, which may be prepared, for example, by methods that are conventional in the art. Examples of such veterinary compositions include those adapted for:

30

- (a) oral administration, external application, for example drenches (e.g.

- 11 -

aqueous or non-aqueous solutions or suspensions); tablets or boluses; powders, granules or pellets for admixture with feed stuffs; pastes for application to the tongue;

- (b) parenteral administration for example by subcutaneous,
5 intramuscular or intravenous injection, e.g. as a sterile solution or suspension; or (when appropriate) by intramammary injection where a suspension or solution is introduced into the udder via the teat;
- (c) topical application, e.g. as a cream, ointment or spray applied to the skin; or
- (d) intravaginally, e.g. as a pessary, cream or foam.

10

It should be understood that in addition to the ingredients particularly mentioned above, the compositions of this invention may include other agents conventional in the art having regard to the type of composition in question, for example, those suitable for oral administration may include such further agents as binders, sweeteners, thickeners,
15 flavouring agents, disintegrating agents, coating agents, preservatives, lubricants and/or time delay agents.

Suitable sweeteners include sucrose, lactose, glucose, aspartame or saccharin. Suitable disintegrating agents include corn starch, methylcellulose, polyvinylpyrrolidone,
20 xanthan gum, bentonite, alginic acid or agar. Suitable flavouring agents include peppermint oil, oil of wintergreen, cherry, orange or raspberry flavouring. Suitable coating agents include polymers or copolymers of acrylic acid and/or methacrylic acid and/or their esters, waxes, fatty alcohols, zein, shellac or gluten. Suitable preservatives include sodium benzoate, vitamin E, alpha-tocopherol, ascorbic acid, methyl paraben, propyl paraben or
25 sodium bisulphite. Suitable lubricants include magnesium stearate, steric acid, sodium oleate, sodium chloride or talc. Suitable time delay agents include glyceryl monostearate or glyceryl distearate.

The invention will now be described with reference to the following Examples.

30 These Examples are not to be construed as limiting the invention in any way.

Experimental Method

It has been suggested that lesions of the brain dopamine systems in mammalian species serve as models for a variety of neuropsychiatric disorders. When lesions are placed at various levels along the ascending dopamine pathways in the brains of experimental animals, there are alterations in dopamine function which are accompanied by both acute and prolonged changes in emotional, motoric and feeding behaviours, each of which has been attributed to a specific biochemical sequelae.

For example, alterations of central catecholamine function, particularly that of the ascending noradrenergic and dopamine systems innervating the striatum have been identified as responsible for underlying schizophrenia(30). The experimental concomitants of motor disorder can be produced in several species by lesioning the ascending dopamine system at any anatomical location extending from the midbrain cell bodies of the substantia nigra to the caudate/putamen nucleus. Depending on the species employed, this can result in loss of appetite and body weight, bradykinesia, loss of orabuccal reflex and even tremor and eventual death. The pathology of the ascending dopamine systems has also been implicated in a more subtle, neuropathology of anorexia nervosa and associated depression on several grounds.

Recent work, and the earlier work of others, reveals that there are many parallels between the clinical syndrome of anorexia nervosa and the experimental model with altered dopamine function employed by the present inventors. Such parallels include i) the mutualisation of food; ii) increased activity in the presence of severe energy store depletion and emaciation; iii) increased motivation toward food with reduced food intake and body weight; iv) hypothermia; and v) altered dopamine function, in particular, the similarities between 6-OHDA induced anorexia and that occurring after amphetamine.

At appropriate concentrations, the neurotoxin 6-hydroxydopamine (hereinafter referred to as "6-OHDA") produces specific and permanent lesions of brain monoamines. Intracranial injections of this compound were used in the Examples to produce models of movement disorders such as Parkinson's disease and schizophrenia. Bilateral lesions of the nigrostriatal pathway result in a vegetative, akinetic syndrome characterised by lack of

- 13 -

voluntary movement, hunched posture and body weight loss concomitant with severe
adipsia and aphagia. As a check on the results, 1-methyl-4-phenyl-1,2,3,6-
tetrahydropyridine (hereinafter referred to as "MPTP") which is also known to cause
Parkinsonism by mechanisms similar to that of 6-OHDA was administered as a second
5 animal model.

In humans, MPTP was first synthesised as a herbicide, similar to paraquat, and
workers exposed to large quantities developed irreversible Parkinsonism, not unlike the
idiosyncratic form of the disease. Then, MPTP was used in the illicit drug market to "cut"
10 morphine and give it an increased boost (e.g. by euphoria). This use resulted in the first
patent to be misdiagnosed as a schizophrenic and maintained on anti-psychotic therapy for
three months. Over time many addicts exposed to MPTP developed Parkinson symptoms.

In the Examples reference will be made to the accompanying drawings in which:
15

Figure 1 is a graph showing the effect constant light exposure on body weight
regulation in rats receiving intra-cerebral injections of 6-OHDA to induce experimental
anorexia and body weight loss in which injections were administered on the day marked
"I" and body weight was plotted with respect to the daily cumulative change for each
20 group. (LL = 24h exposure to light; LD = 12h light, 12h dark cycle.)

Figure 2A is a graph showing the effect of constant light exposure on overall
locomotion during several 10 minute test sessions in an infrared activity chamber in rats
receiving intracerebral injections of 6-OHDA and measurements were taken during the
25 light and dark phases of the light cycle. (LL = 24h exposure to light; LD = 12h light, 12h
dark cycle.)

Figure 2B is a graph showing the effect of constant light exposure on locomotion
during 10 minute test sessions in an infrared activity chamber within 4 days after rats
30 received intracerebral injections of 6-OHDA and measurements were taken during the light
and dark phases of the light cycle. (LL = 24h exposure to light; LD = 12h light, 12h dark
cycle.)

Figure 3 is a graph showing the effect of constant light exposure on the ability to retract a limb during several measurement sessions during the light and dark phases of the light cycle after rats received intracerebral injections of 6-OHDA. (LL = 24h exposure to light; LD = 12h light, 12h dark cycle.)

5

Figure 4 is a graph showing the effect of constant light exposure on the ability to step down during several measurement sessions during the light and dark phases of the light cycle after rats received intracerebral injections of 6-OHDA. (LL = 24h exposure to light; LD = 12h light, 12h dark cycle.)

10

Figure 5 is a graph showing the effect of constant light exposure on the ability to ambulate during several measurement sessions during the light and dark phases of the light cycle after rats received intracerebral injections of 6-OHDA. (LL = 24h exposure to light; LD = 12h light, 12h dark cycle.)

15

Figure 6 is a graph showing the effect of constant light(LL) compared with a cycle of 12hr light/ 12 hr dark (L/D) on a 3hr food and water intake test in animals 6 days after they were injected with intra-cerebral 6-OHDA.

20

Figure 7 is a graph showing the effect of pinealectomy on body weight regulation in rats receiving intra-cerebral injections of 6-OHDA to induce experimental anorexia and body weight loss in which injections were administered on the day marked "I" and body weight was plotted with respect to the daily cumulative change for each group. (PX = pinealectomized animals and SHAM = animals were subjected to control surgery without extracting the pineal.)

25

Figure 8A is a graph showing the effect of pinealectomy on overall locomotion during several 10 minute test sessions in an infrared activity chamber in rats receiving intracerebral injections of 6-OHDA and measurements were taken during the light and dark phases of the light cycle. (PX = pinealectomized animals and SHAM = animals were subjected to control surgery without extracting the pineal.)

30

- 15 -

Figure 8B is a graph showing the effect of pinealectomy on locomotion during 10 minute test sessions in an infrared activity chamber within 4 days after rats received intracerebral injections of 6-OHDA and measurements were taken during the light and dark phases of the light cycle. (PX = pinealectomized animals and SHAM = animals were
5 subjected to control surgery without extracting the pineal.)

Figure 9 is a graph showing the effect of pinealectomy on the ability to retract a limb during several measurement sessions after rats received intracerebral injections of 6-OHDA and measurements were taken during the light and dark phases of the light
10 cycle. (PX = pinealectomized animals and SHAM = animals were subjected to control surgery without extracting the pineal.)

Figure 10 is a graph showing the effect of pinealectomy on the ability to step down during several measurement sessions after rats received intracerebral injections of 6-OHDA and measurements were taken during the light and dark phases of the light cycle. (PX =
15 pinealectomized animals and SHAM = animals were subjected to control surgery without extracting the pineal.)

Figure 11 is a graph showing the effect of pinealectomy on the ability to ambulate during several measurement sessions after rats received intracerebral injections of 6-OHDA and measurements were taken during the light and dark phases of the light cycle. (PX =
20 pinealectomized animals and SHAM = animals were subjected to control surgery without extracting the pineal.)

Figure 12 is a graph showing the effect of pinealectomy compared with animals subjected to control surgery without extracting the pineal on a 3hr food and water intake test in animals 6 days after they were injected with intra-cerebral 6-OHDA and measurements were taken during the first 3hr period after the onset of the dark cycle.
25

Figure 13 is a graph showing the effect of pinealectomy on the tendency of rats to walk into the centre squares of an infrared open field (Athigmotaxis) after receiving intracerebral injections of 6-OHDA and measurements were taken during the light phase

(Mel = Melatonin and Nyl = Nylon.)

Figure 23B is a graph showing the effect of intracerebroventricular implants of melatonin on locomotion during the dark phase of the light cycle during 10 minute test sessions in an infrared activity chamber within 4 days after rats received intraperitoneal injection of MPTP. (Mel = Melatonin and Nyl = Nylon.)

Figure 24 is a graph showing the effect of intracerebroventricular implants of melatonin on the ability to step down during the dark phase of the light cycle within 4 days after rats received intraperitoneal injection of MPTP. (Mel = Melatonin and NYL = Nylon).

Figure 25 is a graph showing the effect of bright light therapy and oral atenolol (50 mg daily) on the ability of a patient with Parkinson's disease to walk 6 metres before and after 2 weeks of treatment.

Figure 26 is a graph showing the effect of bright light therapy and oral atenolol (50 mg daily) on the ability of a patient with Parkinson's disease to touch their toe to their inner knee (x 10). Measurements were taken before treatments commencing after 2 weeks of treatments and 5 weeks after treatments were discontinued.

EXAMPLE 1

The natural release of melatonin may be involved in the development of motor impairment. One method of inhibiting endogenous melatonin release is by placing animals in an environment where they are exposed to bright, constant light. One group of animals was placed in an environment with constant light (minimum intensity=150lux) two weeks after undergoing cannulation of the PLH described as follows:

After several days of control observations, all animals were injected bilaterally with 2µl of an 8µg/µl solution of 6-OHDA. Body weight was measured each day just after the onset of the light cycle and motor performance was measured by assessing the performance of animals in the open field and on three tests routinely used to assess motor function. Open field activity was measured in a PVC box fitted with infrared sensors. The number of beams broken during a 10 minute test period was registered. The three reflex tests employed were latency to retract a limb elevated 25cm above the surface of the test area, latency to step up or down from a raised platform when the rear torso was elevated 30cm above the test area surface and latency to step outside a prescribed area. All tests had an optimal latency cut off point of 30s and were based on extensive validation, use and experience.

A second group of cannulated animals was placed in an environment with a 12hr light/12hr dark cycle. After 20 days of control observations of body weight and motor function, the animals were injected with 6-OHDA as described below in Example 3. Body weight was measured each day after 6-OHDA for 24 days and motor performance was measured on days 2, 4, 14 15.

Figure 1 shows the daily cumulative change in body weight for animals housed in either L/L or L/D was similar for the first 22 days of control observation before the injection of 6-OHDA. After this time, those animals housed in L/D showed a progressively more severe drop in body weight than those in L/L ($p=.001$). Recovery commenced 10 days after 6-OHDA injection in L/L animals while those in L/D were still losing weight at day 44.

- 20 -

The motor activity on all tests of motor function were significantly different between the two groups. In Figure 2A, impairment in the open field was significantly less severe in L/L animals injected with 6-OHDA than those housed in L/D ($p=.05$). As shown in Figure 2A, when tested during the recovery phase of the experiment, the performance of L/L animals was significantly better than that of L/D animals ($p=.035$).

Latency to retract a limb (Figure 3) was only slightly increased by 6-OHDA animals if they were housed in L/L while those housed in L/D showed the classical severe impairment of this reflex. The performance of L/L animals was significantly better than in L/D animals ($p=.000$). Latency to Step was similarly affected with L/L animals showing slight impairment while those in L/D were severely impaired (Figure 4; $p=.009$). Latency to ambulate was only marginally affected by exposure to L/L but with a significant trend by L/L animals in the predicted direction (Figure 5; $p=.089$).

Animals housed in L/L lived longer than those in L/D. As shown in Figure 6, the food intake of animals in the L/L group was significantly higher than that of animals in L/D during a 3 hour test ($p=.025$) while water intake was similar in both groups.

EXAMPLE 2

20

In order to remove the principle source of endogenous melatonin, the pineal gland was surgically removed under anaesthesia. SHAM rats served as controls which were subjected to surgery including anaesthesia, incision, craniotomy, puncturing of the sinus and bleeding, but the pineal was not disturbed. Body weight was measured each day for the course of the experiment and motor reflex control was measured on days 2, 4, 14, 15. 6-OHDA injections were administered as specified in Example 3 except that the injections were made acutely without implanting permanent cannulae, on the days indicated.

As shown in Figure 7, the body weight of animals with PZ was similar to the SHAM animals until they received an intracerebral injection of 6-OHDA. Both groups then lost body weight at a comparable rate on the first 2 days after injection, but then the PX animals increased their weight on days 23 to 30 while the SHAM operated animals

- 21 -

continued to decline during that time and the difference was significant ($p < .05$). Figure 8A shows that the open field performance of PX animals was significantly better ($p = .045$) than that of their SHAM operated counterparts at both times of measurement. PX animals also showed significant trend toward better performance during the test sessions than the
5 SHAM animals (Figure 8B; $p = .063$).

As shown in Figure 13 thigmotaxis, or the tenancy of animals to avoid movement into the centre squares of an open field, was also reduced by pinealectomy. Pinealectomy reduced the associated anxiety resulting in significantly increased movement as compared
10 to SHAM operated controls ($p = .019$).

EXAMPLE 3

In order to produce a sustained central release of melatonin, Regulin® pellets were
15 implanted into the left cerebral ventricle of rats at the time of cannulation of the posterior, lateral hypothalamus (PLH). Control rats were implanted with inert nylon pellets of the same dimensions. This method of melatonin administration was chosen on the basis of studies which demonstrated that peripheral injection produced a mild impairment of motor function which was possible because the injection of a bolus does not approximate the low
20 sustained release characteristics of natural release. Animals were cannulated and tested as described in Example 1.

As shown in Figure 14, the animals implanted with nylon pellets displayed a progressive reduction in body weight for the first four days after 6-OHDA injection and
25 then spontaneous recovery commenced similar to that seen in animals implanted with melatonin. However, animals with melatonin implants showed a more severe loss of body weight on a daily basis from day 16 to the end of the experiment and this impairment was significantly greater than in nylon implanted animals in this four day period ($p = .0143$).

30 As shown in Figures 15A and B, the overall change in open field performance and that occurring during the test session was significantly worse in animals implanted with melatonin ($p = .0022$). The animals implanted with melatonin displayed a reduction in

- 22 -

open field performance which was more than twice as much as the animals implanted with inert nylon. The performance of the animals implanted with melatonin on the 3 motor tests was also slower than the animals implanted with nylon although not significant (Figures 16-18).

5

EXAMPLE 4

Animals in this study were again pinealectomized or subjected to the SHAM operation. Four to eight weeks after the pinealectomy all animals received intraperitoneal injections of MPTP as described in Example 5. Body weight was measured for several days before and 4 days after MPTP. Performance on all motor tests was measured 1hr and 48hrs after MPTP administration.

As shown in Figures 19A and B, PX animals regulated their body weight at a level slightly higher than that of SHAM operated controls. Furthermore, they also lost slightly less weight after MPTP injection than their SHAM operated counterparts, but this difference was not significant.

Figure 20 shows that at 1hr after MPTP treatment animals pinealectomized were more active than SHAM operated controls ($p=.0051$). Test performance was significantly better in PX animals in the open field (Figure 21A; $p=.0354$) and PX animals recovered quicker than SHAMs (Figure 21B; $p=.0114$).

EXAMPLE 5

25

The rats were implanted with intracerebral melatonin pellets or inert nylon as described in Example 3 with the exception that they were not implanted with intrahypothalamic cannulae. After the control performance was assessed, all animals received intraperitoneal injections of MPTP on day 4 (7mg/kg/i.p.). Given that the effects of MPTP are less prolonged and traumatic than 6-OHDA, this provided an opportunity to study the phenomenon of recovery. Body weight was measured daily and motor performance was measured 1h, and 2 days after injection.

- 23 -

As shown in Figure 22A, animals implanted with melatonin did not gain as much weight during the time of observation as those implanted with inert nylon. The difference in rate of weight gain was reduced after the injection of MPTP and this difference is shown in Figure 22B ($p=.0201$) and was significant. As shown in Figure 23A and B, the implantation of melatonin pellets increased the motor impairment seen after MPTP as compared to those animals implanted with nylon (overall performance $p=.0344$; night performance trend, $p=.0638$). As shown in Figure 24 the animals with melatonin implants displayed a significant decrement in the ability to step when assessed during the night ($p=.0238$).

EXAMPLE 6

One patient, diagnosed 3 years earlier with Parkinson's disease was exposed to bright light therapy (1500 lux) for two, 1 hour sessions per day, one before retiring and one immediately upon arising to antagonise melatonin secretion. This patient was also prescribed 50mg of the β -noradrenergic antagonist, Atenolol, before going to bed. The patients performance on motor tests and her body weight were measured before treatment commenced and 2 weeks later.

As shown in figure 25 the time taken to walk a 3 metre path and return was 31.3 seconds before treatment to 13.5 seconds after treatment. Similarly, the time taken to lift her foot to her knee and return it to the floor 10 times went from 58s(R) 65s(L) before treatment to 44 seconds for either leg two weeks after treatment. Similarly, on other motor tests the patient showed improvement after treatment and the memory loss and her mental state improved, permitting her to decrease her daily dose of l-dopa. Her tremor and rigidity also improved. The patient also presented as thin with a poor appetite and unable to gain weight during the course of her disease but gained 3 kilos in body weight after 2 weeks of treatment. Her increased movement permitted her to increase her daily activities and her quality of life greatly improved.

A second patient, diagnosed with Parkinson's disease at least 10 years previously was tested on the same tests as the first patient. The effect that bright light therapy (1000

- 24 -

lux) 1 hour in the morning and 1 hour at night with Atenolol 50 mg before retiring had on the ability to perform leg movements is shown in figure 26.

5 The latency required to touch her knee with her foot and return to the floor 10 times improved dramatically after 5 weeks of treatment. When the patient was taken off the treatment for 5 weeks her performance deteriorated.

Those skilled in the art will appreciate that the invention described herein is susceptible to variations and modifications other than those specifically described. It is to be understood that the invention includes all such variations and modifications. The
5 invention also includes all of the steps, features, compositions and compounds referred to or indicated in this specification, individually or collectively, and any and all combinations of any two or more of said steps or features.

THE CLAIMS:

1. A method for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function which comprises subjecting a patient in need thereof to therapy which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof.
2. A method according to claim 1 wherein said neurological or neuropsychiatric disorder associated with altered dopamine function is selected from movement disorders and psychiatric disorders characterized by anxiety.
3. A method according to claim 2 wherein said neurological or neuropsychiatric disorder associated with altered dopamine is a movement disorder selected from Huntington's chorea, periodic limb movement syndrome, restless leg syndrome, Tourette's syndrome, Sundowner's syndrome, schizophrenia, Pick's disease, Punch drunk syndrome, progressive subnuclear palsy, Korsakow-s (Korsakoff's) syndrome, Multiple Sclerosis, Parkinson's disease, neuroleptic-induced Parkinsonism, malignant syndrome, acute dystonia, stroke, trans-ischaemic attack, akathisia and tardive dyskinesia.
4. A method according to claim 2 wherein said neurological or neuropsychiatric disorder associated with altered dopamine anorexia cachexia or anorexia nervosa.
5. A method according to claim 2 wherein said neurological or neuropsychiatry disorder associated with altered dopamine function is Alzheimer's disease or dementia.
6. A method according to claim 2 wherein said neurological or neuropsychiatric disorder associated with altered dopamine function is panic disorder, agoraphobia, obsessive-compulsive disorder, post traumatic stress disorder, acute stress disorder, generalised anxiety disorder and anxiety disorders due to depression.
7. A method according to any one of claims 1 to 6 wherein said patient is subjected

- 29 -

to external therapy which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof.

5 8. A method according to claim 7 wherein said external therapy comprises light therapy.

9. A method according to any one of claims 1 to 6 wherein said therapy comprises the administration of an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof.

10

10. A method according to claim 9 wherein said agents comprises a melatonin antagonist, β -adrenergic antagonist, a calcium channel blocker or melanocyte stimulating hormone.

15 11. A method according to claim 10 wherein said agent comprises propranolol or atenolol.

12. A method according to any one of claims 1 to 6 wherein said therapy comprises surgical ablation or destruction of the pineal gland.

20

13. A method according to any one of claims 1 to 6 wherein said therapy comprises two or more of external therapy, administration of an agent and surgical ablation or destruction of the pineal gland.

25 14. A method for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function which comprises administering an effective amount of an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof and a drug which alters dopamine function and optionally light therapy to a patient in need thereof.

30

15. A method for the treatment and/or prophylaxis of a neurological or

- 30 -

neuropsychiatric disorder associated with neurological or neuropsychiatric disorder associated with altered dopamine function which comprises administering an effective amount of an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof and light therapy to a patient in need thereof.

5

16. A method for the preclinical diagnosis of a neurological or neuropsychiatric disorder associated with dopamine function which includes the step of administering melatonin to a patient suspected of having such disorder.

10

17. Use of an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof in the manufacture of a medicament for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function.

15

18. A pharmaceutical or veterinary composition for the treatment and/or prophylaxis of a neurological or neuropsychiatric disorder associated with altered dopamine function which comprises an agent which blocks and/or inhibits melatonin, precursors thereof and/or metabolic products thereof in association with a pharmaceutically or veterinary acceptable carrier, diluent, adjuvant and/or excipient.
